

# **Carbohydrates: most abundant biological molecules.**

Monosaccharides, disaccharides, oligosaccharides and polysaccharides.

# Sugars

## **Monosaccharides**

- Are the simplest sugars
- Can be used for fuel
- Can be converted into other organic molecules
- Can be combined into polymers

Monosaccharides are either **aldehydes** or **ketones** with two or more hydroxyl groups.

## The Two Families of Monosaccharides Are Aldoses and Ketoses

Glyceraldehyde,  
an aldotriose

Dihydroxyacetone,  
a ketotriose

D-Glucose,  
an aldohexose

**Triose sugars**  $(C_3H_6O_3)$

**Pentose sugars**  $(C_5H_{10}O_5)$

**Hexose sugars**  $(C_6H_{12}O_6)$

**Aldoses**

Glyceraldehyde

Ribose

Glucose

Galactose

**Ketoses**

Dihydroxyacetone

Ribulose

Fructose

# Monosaccharides Have Asymmetric Centers

Two sugars that differ only in the configuration around one carbon atom are called **epimers**.

# The Common Monosaccharides Have Cyclic Structures

**Monosaccharides of more than four carbons tend to have cyclic structures.**

The formation of these ring structures is the result of a general reaction between alcohols and aldehydes or ketones to form derivatives called **hemiacetals** or **hemiketals**.

Isomeric forms of monosaccharides that differ only in their configuration about the hemiacetal or hemiketal carbon atom are called **anomers**.

Interconvert in aqueous solution by a process called **mutarotation**.

## Chair form of beta-Glucose

Carbon # 1 is the center of a hemiacetal. A carbon with both an ether and alcohol on the same carbon.

- Disaccharides
  - Consist of two monosaccharides
  - Are joined by a glycosidic linkage

# Examples of disaccharides

**(a) Dehydration reaction in the synthesis of maltose.** The bonding of two glucose units forms maltose. The glycosidic link joins the number 1 carbon of one glucose to the number 4 carbon of the second glucose. Joining the glucose monomers in a different way would result in a different disaccharide.

Figure 5.5

**(b) Dehydration reaction in the synthesis of sucrose.** Sucrose is a disaccharide formed from glucose and fructose. Notice that fructose, though a hexose like glucose, forms a five-sided ring.

- Polysaccharides
  - Are polymers of sugars
  - Serve many roles in organisms

# Polysaccharides

## Some Homopolysaccharides Are Stored Forms of Fuel

The most important **storage polysaccharides** are **starch in plant cells** and **glycogen in animal cells**.

**Both polysaccharides occur intracellularly as large clusters or granules.**

Starch and glycogen molecules are **heavily hydrated**, because they have many exposed hydroxyl groups available to **form hydrogen-bond with water**.

0.5  $\mu\text{m}$

(a) Starch: a plant polysaccharide

(b) Glycogen: an animal polysaccharide

**Starch** contains two types of glucose polymer, **amylose and amylopectin**.

**Amylose**: long, unbranched chains of D-glucose residues connected by ( $\alpha 1 \rightarrow 4$ ) linkages.

Such chains vary in molecular weight from a few thousand to more than a million.

**Amylopectin**: highly branched. The glycosidic linkages joining successive glucose residues in amylopectin chains are ( $\alpha 1 \rightarrow 4$ );

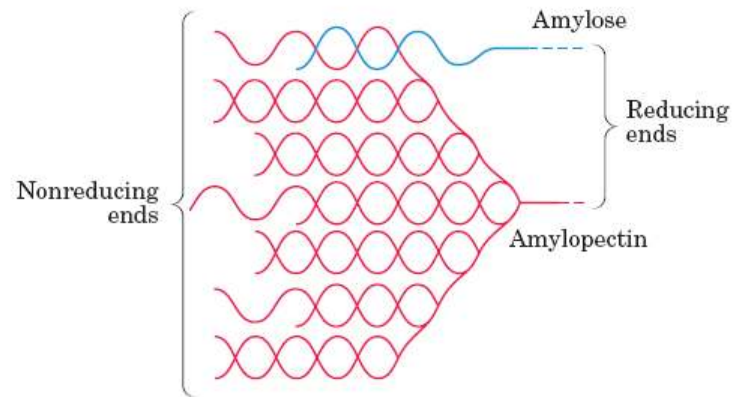

the branch points (occurring every 24 to 30 residues) are ( $\alpha 1 \rightarrow 6$ ) linkages.

(a) amylose

(b)

(c)

**Glycogen:** is the main storage polysaccharide of animal cells.

Like amylopectin, glycogen is a polymer of (alpha 1→4)-linked subunits of glucose, with (alpha 1→6)-linked branches, but glycogen is **more extensively branched** (on average, every 8 to 12 residues) and more compact than starch.

**Glycogen is especially abundant in the liver, also present in skeletal muscle.**

**Why not store glucose in its monomeric form?**

For example hepatocytes store glycogen equivalent to a **glucose concentration of 0.4 M**.

The actual concentration of **glycogen**, which is insoluble and contributes little to the osmolarity of the cytosol, is about **0.01 M**.

If the cytosol contained 0.4 M glucose, the osmolarity would be dangerously elevated, leading to osmotic entry of water that might rupture the cell.

Furthermore, with an intracellular glucose concentration of 0.4 M and an external concentration of about 5 mM (the concentration in the blood of a mammal), the free-energy change for glucose uptake into cells against this very high concentration gradient would be prohibitively large.

# Some Homopolysaccharides Serve Structural Roles

**Cellulose:** In the cell walls of plants.

Linear, unbranched homopolysaccharide, consisting of 10,000 to 15,000 D-glucose units.

**Figure 5.8**

# Some Homopolysaccharides Serve Structural Roles

Linear, unbranched homopolysaccharide, consisting of 10,000 to 15,000 D-glucose units.

glucose residues have the  $\beta$  configuration:  
linked by ( $\beta 1 \rightarrow 4$ ) glycosidic bonds

This difference gives cellulose and amylose very different structures and physical properties.

**Glycogen and starch** ingested in the diet are hydrolyzed by  **$\alpha$ -amylases**, enzymes in saliva and intestinal secretions that break ( $\alpha 1 \rightarrow 4$ ) glycosidic bonds between glucose units.

**Most animals cannot use cellulose as a fuel source, because they lack an enzyme to hydrolyze the ( $\beta 1 \rightarrow 4$ ) linkages.**

Termites readily digest cellulose (and therefore wood), but only because their intestinal tract harbors a symbiotic microorganism, ***Trichonympha***, that secretes **cellulase**.

- Cellulose is difficult to digest
  - Cows have microbes in their stomachs to facilitate this process

Figure 5.9

**Chitin** is a linear homopolysaccharide composed of ***N*-acetylglucosamine** residues in linkage.

The only chemical difference from cellulose is the replacement of the hydroxyl group at C-2 with an acetylated amino group.

Chitin forms extended fibers similar to those of cellulose, and like cellulose cannot be digested by vertebrates.

Chitin is the principal component of the hard exoskeletons of nearly a million species of arthropods—insects, lobsters, and crabs, for example—probably the second most abundant polysaccharide, next to cellulose, in nature.

**FIGURE 7-18** Chitin. (a) A short segment of chitin, a homopolymer of *N*-acetyl-D-glucosamine units in ( $\beta$ 1 $\rightarrow$ 4) linkage. (b) A spotted June beetle (*Pellidnota punetata*), showing its surface armor (exoskeleton) of chitin.

# Dyes or Stains used for carbohydrates

Features	Reagents and dyes (For read)	Object
Tissue parts stained <b>red</b> indicate presence of glycogen	periodic acid Schiff (PAS) method	Glycogen (Animal Starch)
Tissue parts stained <b>blue</b> indicate presence of Mucoid substances.	Alcian blue method	Mucoid Substance (polysaccharide derivatives)
Starch granules stained <b>dark</b> .	<i>Gieson Stain</i>	<b>Starch</b>

# LIPIDS

The biological functions of the lipids are diverse:

**Fats and oils** are the major **stored forms of energy** in many organisms.

**Phospholipids and sterols** are major **structural elements** of biological membranes.

Other lipids, although present in relatively small quantities, play crucial roles such as

- enzyme cofactors,
- electron carriers,
- light-absorbing pigments,
- hydrophobic anchors for proteins,
- “chaperones” to help membrane proteins fold,
- Emulsifying agents in the digestive tract,
- hormones,
- intracellular messengers.

# The fats and oils

(Storage lipids)

almost universally used as stored forms of energy in living organisms

Derived from **fatty acids**.

## Fats

Are constructed from two types of smaller molecules, a **single glycerol** and usually **three fatty acids**

(a) Dehydration reaction in the synthesis of a fat  
Ester linkage

(b) Fat molecule (triacylglycerol)

Figure 5.11

Fatty acids: Carboxylic acids with from 4 to 36 long hydrocarbon chains.

- ◆ Chain is un-branched and fully saturated (contains no double bonds);
- Or
- ◆ Chain contains one or more double bonds.

but are separated by a methylene group:

The double bonds of polyunsaturated fatty acids are almost never conjugated.

Saturated

Unsaturated

### **Cis-configuration**

In nearly all naturally occurring unsaturated fatty acids, the **double bonds are in the cis configuration.**

The nonpolar hydrocarbon chain accounts for the poor solubility of fatty acids in water.

The longer the fatty acyl chain and the fewer the double bonds, the lower is the solubility in water.

The carboxylic acid group is polar (and ionized at neutral pH) and accounts for the slight solubility of short-chain fatty acids in water.

**Melting points** are also strongly influenced by the **length and degree of unsaturation** of the hydrocarbon chain.

At room temperature, the **saturated fatty acids from 12:0 to 24:0 have a waxy consistency**, whereas **unsaturated fatty acids of these lengths are oily liquids**.

**(The first number represent the numbers of carbon and second represents numbers of double bonds)**

This difference in melting points is also due to **different degrees of packing of the fatty acid molecules**.

In the **fully saturated compounds**, free rotation around each carbon–carbon bond gives the hydrocarbon chain great flexibility; **the most stable** conformation is the fully extended form, in which the **steric hindrance of neighboring atoms is minimized**.

These molecules **can pack together tightly in nearly crystalline arrays**, with atoms all along their lengths in van der Waals contact with the atoms of neighboring molecules.

In **unsaturated fatty acids**, a **cis double bond forces a kink** in the hydrocarbon chain.

Fatty acids with one or several such kinks cannot pack together as tightly as fully saturated fatty acids, and their interactions with each other are therefore **weaker**. Because it takes less thermal energy to disorder these poorly ordered arrays of unsaturated fatty acids, they have markedly lower melting points than saturated fatty acids of the same chain length.

- Saturated fatty acids
  - Have the maximum number of hydrogen atoms possible
  - Have **no double bonds**

**Figure 5.12a) Saturated fat and fatty acid**

- Unsaturated fatty acids
  - Have **one or more double bonds**

**Figure 5.12b) Unsaturated fat and fatty acid**

# Triacylglycerol are fatty acid esters of glycerol

**Triacylglycerols**, also referred to as triglycerides, fats, or neutral fats.

Composed of three fatty acids each in ester linkage with a single glycerol.

Glycerol

Because the polar hydroxyls of glycerol and the polar carboxylates of the fatty acids are bound in ester linkages, **triacylglycerols are nonpolar, hydrophobic molecules, essentially insoluble in water.**

1-Stearoyl, 2-linoleoyl, 3-palmitoyl glycerol

# Triacylglycerol provide energy and insulation

In most eukaryotic cells, triacylglycerols form a separate phase of microscopic, oily droplets in the aqueous cytosol, serving as depots of metabolic fuel.

In vertebrates, specialized cells called adipocytes, or fat cells, store large amounts of triacylglycerols as fat droplets that nearly fill the cell.

Triacylglycerols are also stored as oils in the seeds of many types of plants, providing energy and biosynthetic precursors during seed germination.

**Cholesterol**

## Sterols Have Four Fused Carbon Rings

**Sterols** are structural lipids present in the membranes of most eukaryotic cells.

The characteristic structure is the **steroid nucleus**, consisting of **four fused rings**, three with six carbons and one with five.

The steroid nucleus is almost **planar and is relatively rigid.**

**Cholesterol**, the major sterol in animal tissues, is amphipathic, with a polar head group (the hydroxyl group at C-3) and a nonpolar hydrocarbon body (the steroid nucleus and the hydrocarbon side chain at C-17), about as long as a 16-carbon fatty acid in its extended form.

**Cholesterol.** The C-3 hydroxyl group is the polar head group.

**Similar sterols are found in other eukaryotes:**

stigmasterol in plants

ergosterol in fungi.

**Bacteria cannot synthesize sterols**

a few bacterial species can incorporate exogenous sterols into their membranes.

The sterols serve as precursors for a variety of products with specific biological activities.

## Steroid hormones.

**Cholesterol (34)**

**Oestrogen (35)**

**Progesterone (36)**

**Testosterone (37)**

**Bile acids are polar derivatives of cholesterol** that act as detergents in the intestine, emulsifying dietary fats to make them more readily accessible to digestive lipases.

Taurocholic acid  
(a bile acid)

# Vitamins

**Definition** - Organic compound required in **small amounts**. Required for development and Growth

Vitamin A, D, E, K (**Fat soluble**)  
Accumulate in adipose tissue → Toxicity

Retinol (Vitamin A)

Vitamin B1, B2, B3, B5, B6, B7, B9, B12, C  
(**Water soluble**)

Vitamin B2 - riboflavin

# Deficiency caused by Vitamins

Vitamin	Chemical Name	Deficiency Diseases
<b>Fat soluble Vitamins</b>		
A	Retinol, Retinal, Retinoic acid	Night-blindness and keratomalacia
D	Ergocalciferol (D <sub>2</sub> ), Cholecalciferol (D <sub>3</sub> )	Rickets and Osteomalacia
E	Tocopherol	Mild hemolytic anemia in newborn infants
K	Phylloquinone (K <sub>1</sub> ), Menaquinones (K <sub>2</sub> )	Bleeding diathesis
<b>Water soluble vitamins</b>		
B <sub>1</sub>	Thiamine	Beriberi
B <sub>2</sub>	Riboflavin	Ariboflavinosis
B <sub>3</sub>	Niacin, Niacinamide	Pellagra
B <sub>5</sub>	Pantothenic acid	Paresthesia
B <sub>6</sub>	Pyridoxine, Pyridoxamine, Pyridoxal	Anemia peripheral neuropathy
B <sub>7</sub>	Biotin	Dermatitis
B <sub>9</sub>	Folic acid, Folinic acid	Neural tube defects
B <sub>12</sub>	Cyanacobalamine	Megaloblastic anemia
C	Ascorbic acid	Scurvy

## Top Food Sources Rich in Vitamins

Vitamin A	Carrots, broccoli, sweet potato, leafy greens, cheddar cheese, eggs
Vitamin D	Fatty fish (catfish, salmon, tuna, sardines), eggs, liver, mushrooms
Vitamin E	Sunflower oil, nuts, tomatoes, pumpkin, sweet potato, asparagus
Vitamin K	Spinach, chard, broccoli, Brussels sprouts, avocado, kiwi, grapes
B1: Thiamine	Yeast, pork, whole grains, oatmeal, sunflower seeds, brown rice
B2: Riboflavin	Yeast, liver, wheat bran, eggs, meat, milk, cheese.
B3: Niacin	Chicken, beef, fish, whole grains, nuts, tomatoes, broccoli, carrots
B5: Pantothenate	Whole grains, beans, eggs, meat, avocado, broccoli, yogurt.
B6: Pyridoxine	Spinach, bell peppers, cauliflower, banana, celery, cabbage, cod
B7: Biotin	Egg yolk, liver, peanuts, Swiss chard, strawberries, raspberries
B9: Folic Acid	Spinach, asparagus, beans, peas, egg yolks, sunflower seeds, yeast
B12: Cobalamins	Liver, oysters, crab, clams, Swiss cheese, beef, egg, milk
Vitamin C	Guava, parsley, kiwi, broccoli, B. sprouts, strawberry, oranges.

## **Coenzymes**

B1: Thiamine pyrophosphate

B3: NAD, NADP

B6: Pyridoxal phosphate

B9: Tetrahydrofolate

## **Energy generating Vitamins**

B1,

B2,

B3,

B5,

B7

## **Hematopoietic**

B9 and B12

## **Others**

B6: Neurotransmitters

Amino acid

metabolism

- In a polar covalent bond
  - The atoms have differing electronegativities
  - Share the electrons unequally

Because oxygen (O) is more electronegative than hydrogen (H), shared electrons are pulled more toward oxygen.

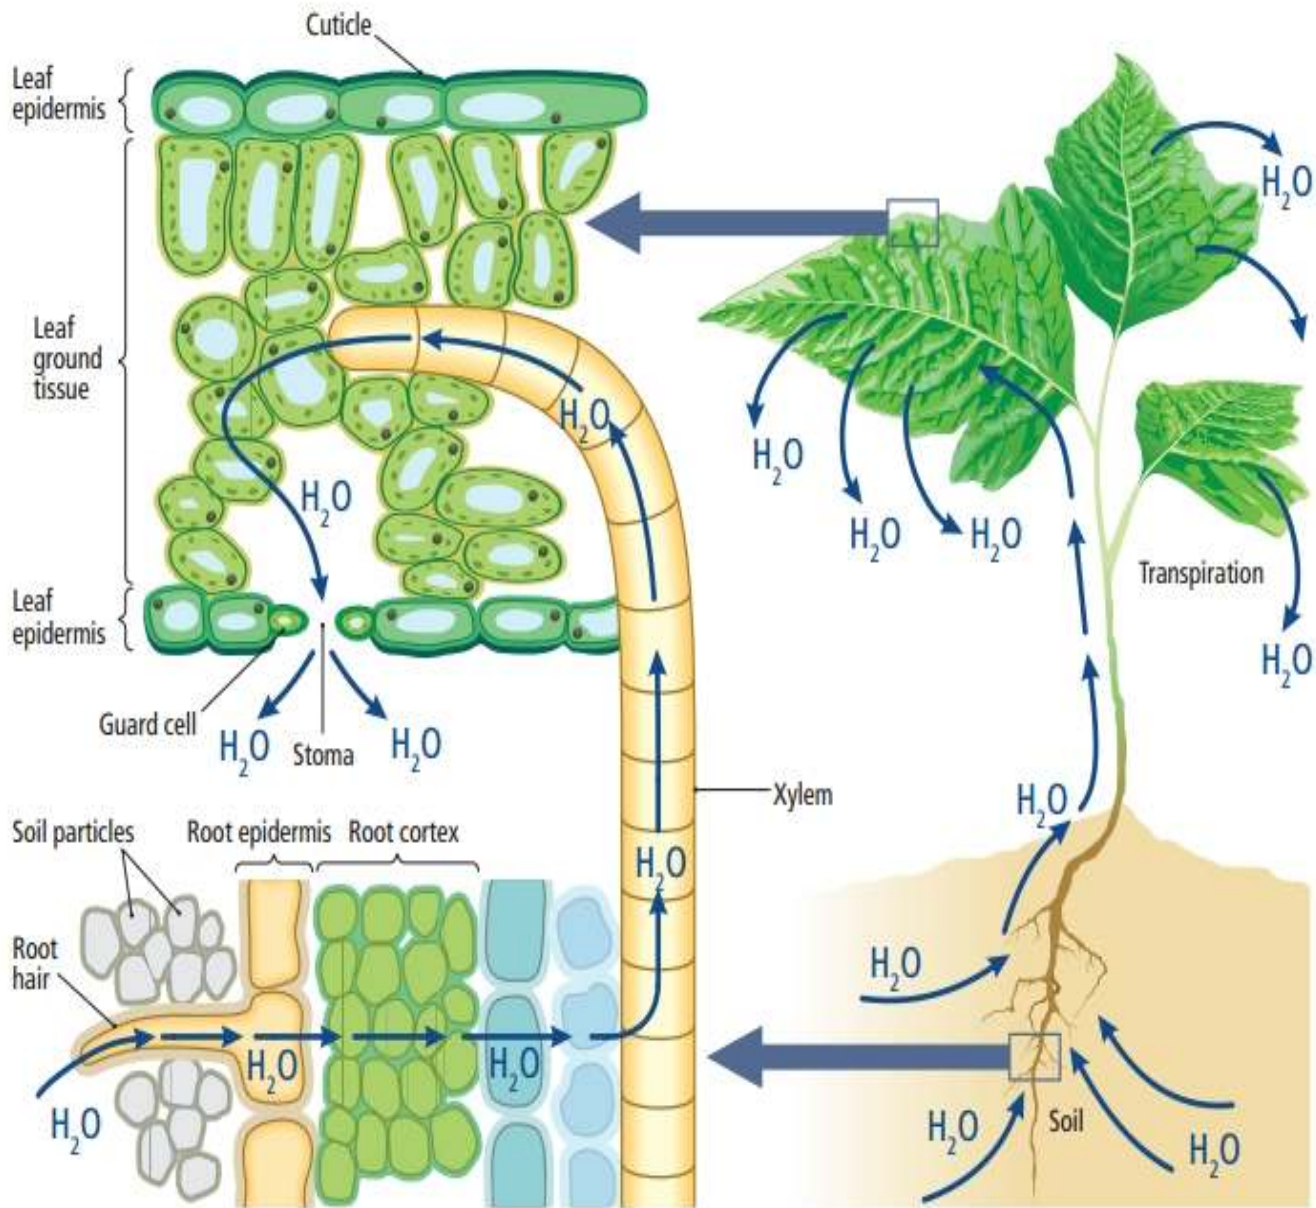

This results in a partial negative charge on the oxygen and a partial positive charge on the hydrogens.

Figure 2.12

# Emergent properties of water

## (Due to Hydrogen bonding)

- Cohesive behavior
  - (Water is transported in plants)
  - (High surface tension)
- Ability to moderate temperature
  - 1g H<sub>2</sub>O to change its temp by one deg= 1cal
  - Alcohol=0.6 cal
  - Iron=0.1 cal
  - **Stabilization of marine life**
  - High vaporization heat =580 cal/g (=2x that of NH<sub>3</sub> or alcohol)
  - **Overheating is avoided**
- Expansion upon freezing
  - Density of frozen water is less as compared to liquid
- Versatile solvent

# Essential Elements of Life

## Importance of Trace Elements in Life:

Iodine deficiency in the diet causes the thyroid gland to grow to abnormal size, a condition called goiter.

Where it is available, iodized salt has reduced the incidence of goiter.

**Table 2.1 Naturally Occurring Elements in the Human Body**

Symbol	Element	Atomic Number (see p. 33)	Percentage of Human Body Weight
<b>Elements making up about 96% of human body weight</b>			
O	Oxygen	8	65.0
C	Carbon	6	18.5
H	Hydrogen	1	9.5
N	Nitrogen	7	3.3
<b>Elements making up about 4% of human body weight</b>			
Ca	Calcium	20	1.5
P	Phosphorus	15	1.0
